EDGE was initially developed in order to provide data service at higher rates than GSM or GPRS, by making use of multi-phase modulation (such as 8-PSK) instead of binary GMSK. However, the structure of the proposed RLC/MAC blocks for data transmission do not allow for the efficient use of the available radio resources for voice transmission. Furthermore, due to the use of 8-PSK more powerful channel coding is required in order to maintain certain levels of voice quality.

The use of more powerful channel encoding techniques generates a larger number of encoded bits. If the number of bits encoded exceeds the number of bit spaces available, then puncturing is usually applied to remove certain bits. A performance trade off therefore exists between providing a powerful channel coding technique, but minimising the number of bits to be punctured.

It is therefore an object of the present invention to provide an improved encoding technique suitable for efficient channel encoding of voice on an EDGE network.

Summary of the Invention

According to the present invention there is provided a method of encoding at least two sets of data bits into a single encoded block, wherein each set of data bits includes a primary set of bits to be encoded and a secondary set of bits to remain unencoded, wherein the encoding technique requires a set of code terminating bits to be added to the primary set of bits, the method comprising: combining the two sets of primary bits; and encoding the combined two sets of primary bits, whereby one set of code terminating bits is added to the combined two sets of primary bits.

The two sets of data bits may each include a header portion and a payload portion, the payload portion comprising encoded speech. The encoding step may be a channel encoding step for encoding the at least two sets of data bits for transmission on a packet switched network. The data bits may be for

7. The encoder of claim 5 or claim 6 wherein at least two sets of data bits each include a header portion and a payload portion, the payload portion including encoded speech and the single encoded block being an RLC/MAC block.

Re Item V

Reasoned statement under Rule 66.2(a)(ii) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement

- 1. The invention concerns a method of encoding bits suitable for use in an EDGE mobile communications system. The closest prior art is formed by the commonly known specification for EDGE systems, based on the GSM air interface. In the GSM system, voice signals are encoded with class I and class II bits (primary and secondary bits), according to their importance, the class I bits being encoded subsequently by convolutional encoder. In EDGE, the use of 8-PSK allows a much higher data rate than GSM, but for voice more powerful channel coding is required to maintain voice quality level.
- 2. The aim of the invention is to provide an efficient coding technique suitable for the encoding of voice on an EDGE network.
- The invention differs over prior art EDGE systems in that two sets of primary bits 3. are combined and encoded together, thus requiring only one set of terminating bits.
- 4. None of the prior art documents suggests the combining and encoding of two sets of primary bits derived from two sets of bits each having primary and secondary bits. D1 refers to a system using the known GSM air interface. Although it describes class 1a and class 1b bits, these are not derived from two sets of bits each having primary and secondary bits, and in any case they are not encoded together. D2 has a transmission system for voice an image data, but each block is either a voice, image or control block and are CRC coded individually, thus no sets are combined for joint coding. D3 is concerned only with error detection.

Compared with the available prior art, the subject-matter of claim 1 is therefore considered both novel and to involve an inventive step (Articles 33(1)-(3) PCT).

5. Claim 5 is for an encoder with features corresponding to method claim 1; claim 6 is for a packet switched network including the encoder of claim 5. Claims 2-4 and 7 are dependent on either claims 1 or 5.

Claims 2-7 therefore also meet the requirements for novelty and inventive step (Articles 33(1)-(3) PCT).

Re Item VII

Certain defects in the international application

1. The features of the claims are not provided with reference signs placed in parentheses (Rule 6.2(b) PCT).

Re Item VIII

Certain observations on the international application

1. Claim 1 does not meet the requirements of Article 6 PCT; the reason for this objection is the following:

Claim 1 is broader than justified by the scope of the description and drawings: claim 1 is thus not supported by the description. The description relates clearly to EDGE systems, the aim of the invention being defined on page 2 as originally filed as "to provide an improved encoding technique suitable for efficient channel encoding of voice on an EDGE network". Since the whole impression conveyed by the application is that the invention relates to a specific system, and it is not apparent that a skilled person could extend the teaching across the whole of the field of encoding data having primary and secondary sets of bits, then objection arises (cf PCT Guidelines III-6.4).

EXAMINATION REPORT - SEPARATE SHEET

Moreover claim 1 is not clear; without the limitations to specifically EDGE networks and to voice data, it is entirely unclear how to interpret the scope of the terms "primary" and "secondary" set of bits. Eg in a data transmission network the primary bits could be headers and the secondary bits a data payload, which is clearly not what is described in the present application.

Claim 1 should therefore have been limited to a method for use in an EDGE network, wherein voice signals are coded in the form of a set of bits, the set of bits comprising a primary and a secondary sets of bits.

2. Claim 5 lacks clarity and support by the description for the same reasons (Article 6 PCT).

Box iii TEXT OF THE ABSTRACT (Continuation of Item 5 of the first sheet)

A method of encoding at least two sets of data bits into a single encoded block is provided, wherein each set of data bits includes a primary set of bits to be encoded and a secondary set of bits to remain unencoded, wherein the encoding technique requires a set of code terminating bits to be added to the primary set of bits; the method comprising: combining the two sets of primary bits, whereby one set of code terminating bits is added to the combined two sets of primary bits.

The two sets of data bits may each include a header portion and a payload portion, the payload portion comprising encoded speech. The encoding step may be a channel encoding step for encoding the at least two sets of data bits for transmission on a packet switched network. The data bits may be for transmission on an EDGE packet switched network, wherein the at least two sets of data bits are encoded into a single RLC/MAC block.
